

Vibration characteristics of functionally graded cylindrical shells: A study of structural dynamics

The problem of shell vibrations has gained much importance due to their uses in different engineering and technological fields. They have been extensively used for the purpose of load carrying in the past. Recently they have acquired a paramount and valuable place in practical applications constructing gas cylinders, pressure vessels, boilers, pipe-lines, submarines, tunnels, missiles, and so on. Dynamic response of fluid-filled cylindrical shells is of primary importance for the design of pressure vessels, fluid tanks of liquid propellant rockets, seismic studies of liquid storage tanks and so on. Study of interaction between shell structure and fluid is great interest during vibration. Interaction of functionally graded materials and elastic foundation is another important issue related to mechanical behavior. It can be concluded that cylindrical shells are fundamental and core-structural elements in various fields of engineering and technology and their study shows the significance towards economic growth of the country.
